AutoPanelSizer

Description

The AutoPanelSizer software determines optimized cutting layouts for the production of rectangular parts from rectangular raw material and minimizes waste, production times and manufacturing costs. AutoPanelSizer generates layouts that can be produced with straight, continuous (guillotine) cuts. In case of interlinked plants, the maximum number of cutting stages is taken into account. Thereby, the software models a common cutting technology, applied in the machining of wood and also in the glass, metal, and plastics manufacturing industries.

AutoPanelSizer can compute layouts with recuts after the last stage and head cuts in the first stage (see examples 2 and 3, respectively). The software is able to comply with miscellaneous constraints given by machine or material properties.

Available remainders and various sizes of raw sheets can be included in the optimization. The computation of a typical cutting layout takes from only a few seconds to just a few minutes.

Impact on production

In the optimization process, the software considers both production times and manufacturing costs. It can off-set time-consuming processes, such as head cuts or the storage of remainders, against a more efficient material utilization. By combining identical cutting plans into packages, simultaneous cuts are feasible thereby reducing production time. AutoPanelSizer offers various possibilities to control the generation of such package cuts.

Furthermore, each part to be produced may be assigned to a part group. This allows for destacking restrictions as well as requests regarding a production sequence to be taken into account. In connection with part groups, the optimization can also be carried out across different material types.
Anticipatory planning by optional overproduction

In AutoPanelSizer, parts may be declared as required (compulsory) or optional. The former have to be placed on the cutting layouts, the latter are only placed if they fit well and improve the yield. For example, parts that are needed the next day can be declared as required, while parts that are needed later can be declared as optional. This anticipatory production improves the efficiency of the cutting layouts and reduces the overall material consumption.

Selected Features

- Consideration of production times and manufacturing costs
  - Offsetting package or head cuts against yield improvement
- Minimum and maximum lengths of cuts and saw feeds
  - for strips, parts, identical strips and end sections
  - for mapping restrictions caused by machine widths, transport devices, grippers, etc.
- Setting the feed direction
- Individual trimming at the panel edges
- Required and optional demand
- Grain of sheets and parts
- Optimization across multiple material types
- Remainders
  - Minimum and maximum size
  - Off-setting against yield and optional parts
  - Preferred use of existing remainders
- Head cuts
- Recuts
- Package cuts
- Part groups (also cross-material) to model destacking restrictions

Software

AutoPanelSizer is distributed as a pure optimization kernel. It is designed to be integrated into other applications, e.g. plant control or ERP systems, through an XML-interface. Alternatively, AutoPanelSizer can be employed via a file interface or as a server application. The software is available for all current Microsoft Windows PC operating systems. Based on the latest research results, Fraunhofer SCAI constantly improves and enhances AutoPanelSizer. AutoPanelSizer benefits from the expertise of the institute in optimization.
